

Near Field Communication Technology

For Prelims: NFC, Wi-Fi, Bluetooth Technologies.

For Mains: IT and Computers.

Why in News?

Google Pay has recently launched a new feature in India, 'Tap to pay for UPI', in collaboration with Pine Labs. The feature makes use of **Near Field Communication (NFC) technology.**

- The functionality will allow users with NFC-enabled Android smartphones and <u>UPI (Unified Payments Interface)</u> accounts linked to Google Pay to carry out transactions just by tapping their phones on any Pine Labs Android point-of-sale (POS) terminal across the country.
- The process is much faster compared to scanning a QR code or entering the UPI-linked mobile number which has been the conventional way till now.
- In February 2022, Apple introduced Tap to Pay on the iPhone.

What is NFC and how does it work?

- NFC is a short-range wireless connectivity technology that allows NFC-enabled devices
 to communicate with each other and transfer information quickly and easily with a single touch
 whether to pay bills, exchange business cards, download coupons, or share a document.
- NFC transmits data through electromagnetic radio fields, to enable communication between two devices. Both devices must contain NFC chips, as transactions take place within a very short distance.
 - NFC-enabled devices must be either physically touching or within a few centimetres from each other for data transfer to occur.
- In 2004, consumer electronics companies, Nokia, Philips and Sony together formed the NFC Forum, which outlined the architecture for NFC technology to create powerful new consumer-driven products.
- Nokia released the first NFC-enabled phone in 2007.

What are the other applications of NFC technology?

- It is used in **contactless banking cards to perform money transactions** or to generate contact-less tickets for public transport.
 - Contactless cards and readers use NFC in several applications from securing networks and buildings to monitoring inventory and sales, preventing auto theft, and running unmanned toll booths.
- It is present in speakers, household appliances, and other electronic devices that are controlled through smartphones.
- It also has an application in healthcare, to monitor patient stats through NFC-enabled wristbands. NFC is used in wireless charging too.

How safe is this technology?

- NFC technology is designed for an operation between devices within a few centimetres from each other. This makes it difficult for attackers to record the communication between the devices compared to other wireless technologies which have a working distance of several metres.
- The user of the NFC-enabled device determines by the touch gesture which entity the NFC communication should take place with, making it more difficult for the attacker to get connected.
- The security level of the NFC communication is by default higher compared to other wireless communication protocols.
- Since the receiving device reads data the instant one sends it, NFCs also reduce the chance of human error.

Where does it stand in comparison to other wireless technologies?

- The IrDa (Infrared) technology is a short range (a few metres) connection based on the exchange of data over infrared light where the two communication devices must be positioned within a line of sight. Today, this technology is mainly used for remote control devices.
- For larger data communication with computer devices this technology was replaced by Bluetooth or WiFi connections.
 - However, for these technologies' receiver devices need their own power supply due to the larger working distance.
 - Therefore, the receiving device cannot be powered by the Radiofrequency (RF) field like in NFC.
 - Another consequence of the larger working distance is the need for the user to configure their device and to pair them together for communication. Connection cannot be initiated by a simple touch gesture like in NFC.

Note

Bluetooth: Developed in the late 1990s, it is a technology designed to enable short-range wireless communication between electronic devices, such as between a laptop and a smartphone or between a computer and a television.

- Bluetooth works by using radio frequencies, rather than the infrared spectrum used by traditional remote controls. As a result, Bluetooth eliminates the need not only for a wire connection but also for maintaining a clear line of sight to communicate between devices.
- Bluetooth works at 2.4GHz frequency.

Wi-Fi (Wireless Fidelity): It is similar to Bluetooth in that it also uses radio waves for high-speed data transfer over short distances without the need for a wire connection.

- Wi-Fi works by breaking a signal into pieces and transmitting those fragments over multiple radio frequencies. This technique enables the signal to be transmitted at a lower power per frequency and also allows multiple devices to use the same Wi-Fi transmitter.
- Initially developed in the 1990s, Wi-Fi has undergone several standardization processes, approved by the Institute of Electrical and Electronics Engineers (IEEE), to allow for greater bandwidth in data transfer.
- Wi-Fi based networks work at 2.4, 3.6 and 5 GHz.

UPSC Civil Services Examination, Previous Year Questions (PYQs)

Q. With reference to 'LiFi', recently in the news, which of the following statements is/are

correct? (2016)

- 1. It uses light as the medium for high speed data transmission.
- 2. It is a wireless technology and is several times faster than 'WiFi'.

Select the correct answer using the code given below:

- (a) 1 only
- (b) 2 only
- (c) Both 1 and 2
- (d) Neither 1 nor 2

Ans: (c)

- Li-Fi stands for Light Fidelity and is a Visible Light Communications (VLC) system which runs wireless communications that travels at very high speeds. The term was coined by University of Edinburgh Professor Harald Haas during a TED Talk in 2011. Haas envisioned light bulbs that could act as wireless routers.
- Wi-Fi technology uses radio waves for transmission, whereas Li-Fi utilizes light waves. Wi-Fi works well for general wireless coverage within the building/ campus/compound, and Li-Fi is ideal for high density wireless data coverage in a confined area or room and is free from interference issues unlike the Wi-Fi. Speed of data transmission for Li-Fi is approximately 1 Gbps and for Wi-Fi IEEE 802.11n is approximately 150 Mbps. Hence, statements 1 and 2 are correct.
- Therefore, option (c) is the correct answer.

Q. What is the difference between Bluetooth and Wi-Fi devices? (2011)

- (a) Bluetooth uses 2.4 GHz radio frequency band whereas Wi-Fi can use 2.4 GHz or 5 GHz frequency band
- (b) Bluetooth is used for Wireless Local Area Networks (WLAN) only, whereas Wi-Fi is used for Wireless Wide Area Networks (WWAN) only
- (c) When information is transmitted between two devices using Bluetooth technology, the devices have to be in the line of sight of each other, but when Wi-Fi technology is used the devices need not be in the line of sight of each other
- (d) The statements (a) and (b) given above are correct in this context

Ans: (a)

Q. Consider the following: (2010)

- 1. Bluetooth device
- 2. Cordless phone
- 3. Microwave oven
- 4. Wi-Fi device

Which of the above can operate between 2.4 and 2.5 GHz range of radio frequency band?

- (a) 1 and 2 only
- (b) 3 and 4 only
- (c) 1. 2 and 4 only
- (d) 1, 2, 3 and 4

Ans: (d)

 Bluetooth is a wireless technology for exchanging data between fixed and mobile devices over short distances. The working frequency band is 2.400 to 2.485 GHz. Hence, 1 is correct.

- A cordless telephone works in the frequency band of 2.4 GHz and 5.8 GHz. **Hence, 2 is correct.**
- Microwave oven uses frequencies of 2.45 GHz. Hence, 3 is correct.
- Wi-Fi is technology for radio wireless local area networking of devices. Wi-Fi most commonly uses the 2.4 GHz band. **Hence, 4 is correct.**
- Therefore, option (d) is the correct answer.
