

Groynes

Source: TH

Groynes are **low-lying wood or concrete structures** which are situated out to sea from the shore.

- They are designed to trap sediment, dissipate wave energy, and restrict the transfer of sediment away from the beach through longshore drift.
 - **Longshore drift is caused** when prevailing winds blow waves across the shore at an angle that carries sediment along the beach.
 - Groynes slow the process of erosion at the shore.
- They can also be permeable or impermeable, permeable groynes allow some sediment to pass through and some longshore drift to take place.
 - However, impermeable groynes are solid and prevent the transfer of any sediment.
- They are very effective at protecting the coastline in the short-term as they are immediately
 effective as opposed to some longer-term soft engineering methods.
 - However, they are **often intrusive and can cause issues** elsewhere in other areas along the coastline.
