

Antarctica's Deep Winter Heatwaves

[Source: IE](#)

Why in News?

Recently, Antarctica has been experiencing a significant **deep-winter heatwave**, marking the second instance of record-breaking temperatures in two years.

- Ground temperatures have risen by an average of 10 degrees Celsius above normal since mid-July 2024, with some areas experiencing increases of up to 28 degrees Celsius.

//

What are the Causes of Deep-Winter Heat Waves in Antarctica?

- **Weakening of the Polar Vortex:**
 - The **polar vortex** (also known as **polar pig**) is a large **area of low pressure** and **cold air** surrounding both of the Earth's poles.

- The term "**vortex**" refers to the **counterclockwise flow of air** that helps keep the **colder air near the Poles**. It always exists near the poles, but **weakens in summer and strengthens in winter**.
- **Higher temperatures** and **powerful atmospheric waves** (periodic disturbances in the fields of atmospheric variables) **disrupted the vortex**.
 - This allowed **cold air to escape and warm air from above to descend**. The arrival of this warm air led to a rise in temperatures in the region.
- **Reduction of Antarctic Sea Ice:**
 - Antarctic **sea ice** has reached historically low levels, **reducing its ability to reflect solar energy** and **act as a barrier between cold air and warmer waters**. This loss contributes to **rising global temperatures**.
- **High Rate of Global Warming:**
 - **Antarctica** is experiencing **warming at a rate nearly double** that of the global average, estimated at **0.22 to 0.32 degrees Celsius per decade**.
 - As per **IPCC** estimates **Earth** as a whole is warming at the rate of **0.14-0.18 degrees Celsius per decade**.
 - This **accelerated warming** is primarily driven by **anthropogenic climate change**, which exacerbates the effects of natural climate variability.
- **Impact of the Southern Ocean:**
 - The **warming Southern Ocean absorbs more heat** due to reduced sea ice, creating a feedback loop that **raises air temperatures over Antarctica** and increases the risk of extreme weather events.

The Science Behind the Polar Vortex

The polar vortex is a large area of low pressure and cold air surrounding the Earth's North and South poles. The term vortex refers to the counterclockwise flow of air that helps keep the colder air close to the poles (left globe). Often during winter in the Northern Hemisphere, the polar vortex will become less stable and expand, sending cold Arctic air southward over the United States with the jet stream (right globe). The polar vortex is nothing new — in fact, it's thought that the term first appeared in an 1853 issue of E. Littell's *Living Age*.

What are the Consequences of Heat Waves in Antarctica?

- **Accelerated Ice Melt:** Antarctica's rising winter temperatures are **accelerating ice mass loss**, with recent decades seeing a **280% increase** compared to the 1980s and 1990s.
 - In March 2022, a **heat wave caused a section of ice of around 1300 square**

kilometres to collapse, highlighting the significant risk of rising global sea levels.

- **Global Sea Level Rise:** The Antarctic ice Sheet covers **98% of Antarctica** and contains **over 60% of the world's freshwater**.
 - A slight increase of a few feet in sea levels could result in the displacement of around **230 million people** residing **within 3 feet of existing high tide lines**, posing a significant threat to coastal cities and ecosystems.
- **Disruption of Ocean Circulation:** The influx of freshwater from melting ice alters the **salinity and density of ocean waters**, slowing down **global ocean circulation**.
 - A 2023 study revealed that this slowdown **weakens the ocean's capacity to store and transport heat, carbon, and nutrients**, which are essential for climate regulation. **Reduced ocean circulation decreases heat and CO2 absorption**, intensifying global warming and increasing the frequency of **extreme weather events** that affect **ecosystems** and human populations worldwide.
- **Ecosystem Disruption:** Temperature changes and **ice loss disrupt local ecosystems, threatening species** dependent on stable ice, leading to biodiversity loss and altering global food webs.
 - For example species like **polar bears** and **penguins** rely on **stable ice for survival**.
- **Feedback Loops:** Melting ice reduces sunlight reflection (**albedo effect**), increasing heat absorption by oceans and land, which accelerates further ice melt, creating a feedback loop that worsens climate change.
 - **Albedo** is an expression of the **ability of surfaces to reflect sunlight** (heat from the sun).

OCEAN WARMING

The ocean absorbs most of the excess heat due to global warming caused by greenhouse gas (GHG) emissions, leading to rising ocean temperatures

Increase in Ocean Temperature

1.2°C from 1950 to 2020

Projected to Future Increase

1.7°C to 3.8°C from 2020 to 2100

Impact of Ocean Warming

- ⌚ **Sea Level Rise:** Warmer water expands, causing sea levels to rise
- ⌚ **Coral Bleaching:** Corals expel the algae (*zooxanthellae*) living in their tissues and turn completely white
- ⌚ **Ocean Acidification:** Ocean absorbs ~1/4th of total CO₂, thus making it more acidic (non-metallic oxides - acidic in nature)
- ⌚ **Impacts on Marine Life:** Causes many marine species to shift towards the poles and disrupts food webs
- ⌚ **Impacts on Climate Patterns:** Influences atmospheric circulation patterns, such as El Niño and La Niña & extreme weather events

Causes of Ocean Warming (due to Global Warming)

- ⌚ **GHG Emissions:** Fossil fuels burning releases CO₂ and GHG
- ⌚ **Deforestation:** Lesser trees → More CO₂ & GHG → Global Warming → Warming of Ocean
- ⌚ **Industrial Activities:** Emit various pollutants that contribute to greenhouse effect
- ⌚ **Agricultural Practices:** Produces methane and nitrous oxide – potent greenhouse gases
- ⌚ **Heat Absorption by Oceans:** Oceans absorb ~90% of excess heat generated by GHGs

UPSC Civil Services Examination, Previous Year Question (PYQ) :

Q. With reference to the water on the planet Earth, consider the following statements:(2021)

1. The amount of water in the rivers and lakes is more than the amount of groundwater.
2. The amount of water in polar ice caps and glaciers is more than the amount of groundwater.

Which of the statements given above is/are correct?

- (a) 1 only
- (b) 2 only
- (c) Both 1 and 2
- (d) Neither 1 nor 2

Ans: (b)
