

## The Global Nitrous Oxide Budget 2024

**For Prelims:** Nitrogen pollution, [UNEP](#), [Nitrogen-based fertiliser](#), [Ammonia](#), [Air pollution](#), Methemoglobinemia, [Stratospheric ozone layer](#).

**For Mains:** Sources of Nitrogen Pollution, Major Impacts of Nitrogen Pollution, Major Compounds of Nitrogen and their Effects.

[Source: TH](#)

### Why in News?

According to a new study by the **Global Carbon Project (GCP)** titled, “**Global Nitrous Oxide Budget (1980-2020)**”, the emissions of nitrous oxide have been rising continuously between 1980 and 2020.

- A study found that in 2021 and 2022, nitrous oxide was released into the air faster than ever before, even though we need to cut [greenhouse gasses](#) to fight [global warming](#).

### About GCP Study

- **Global Carbon Project (GCP)** is an **organisation** established in 2001 which conducts studies that seek to quantify global greenhouse gas emissions and their causes.
  - This study by GCP analyses the **impact of human activity on greenhouse gas emissions** and earth systems and **quantifies emissions of carbon dioxide, methane and nitrous oxide (3 major greenhouse gases)** to inform public policy and international action.
- **It involved the examination of global data for all major economic activities that lead to nitrous oxide emissions from 18 anthropogenic and natural sources and 3 absorbent “sinks” of global nitrous oxide.**

### Absorbent “Sinks” of Nitrous Oxide:

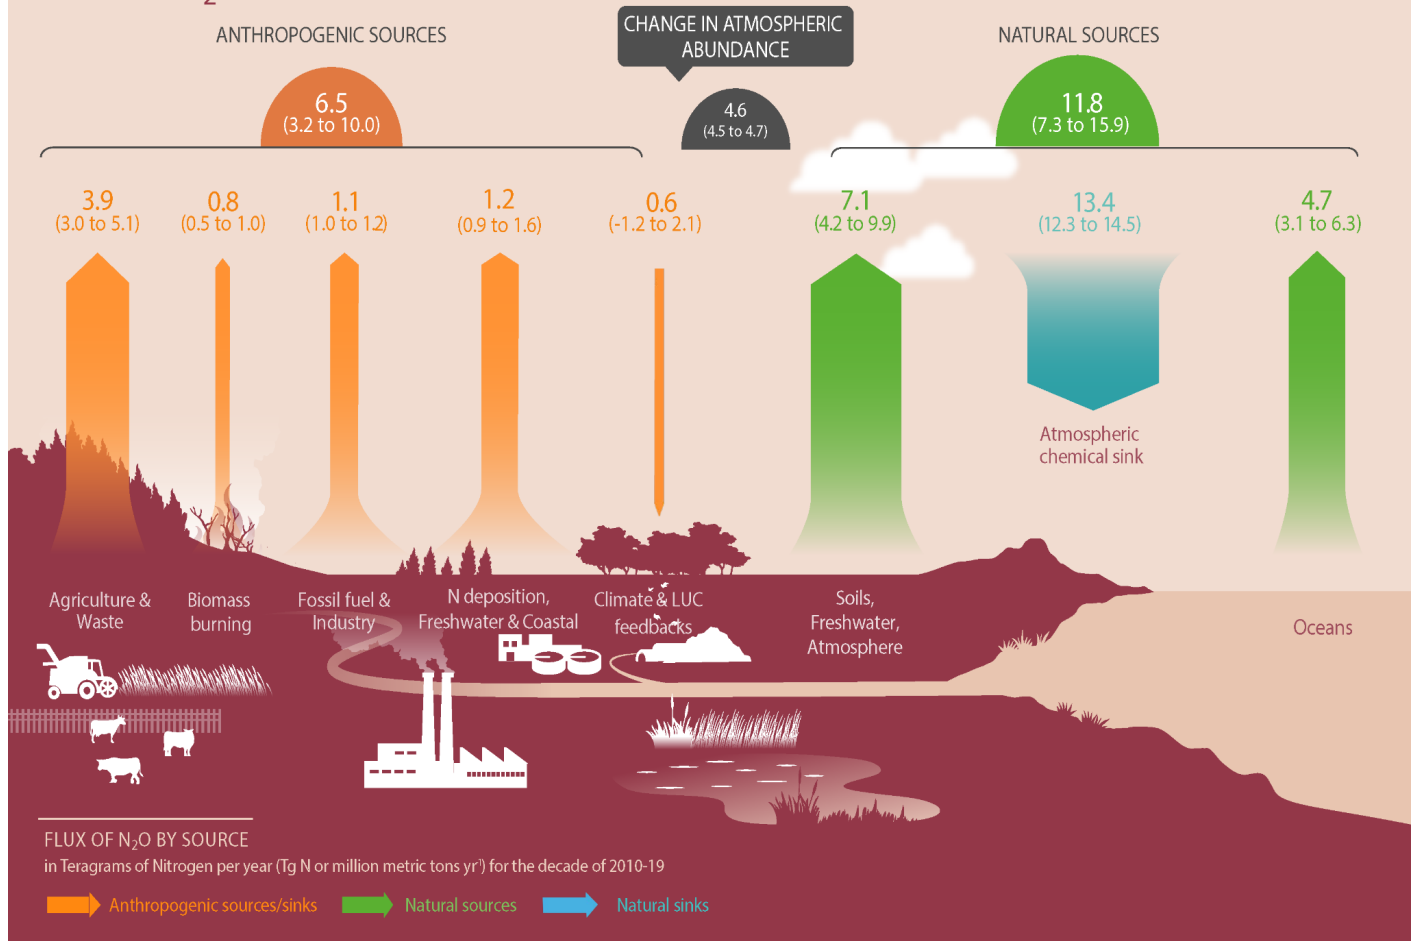

- **Soils:**
  - Soils act as a significant **sink for N<sub>2</sub>O**. Microbial processes in soils can consume and **reduce N<sub>2</sub>O emissions**.
  - **Denitrifying bacteria convert N<sub>2</sub>O to nitrogen gas (N<sub>2</sub>)** under anaerobic conditions, effectively **removing it from the atmosphere**. The balance between nitrification (which produces N<sub>2</sub>O) and denitrification determines the net soil sink capacity.
- **Oceans:**
  - Deeper and **subsurface oceans absorb N<sub>2</sub>O from the atmosphere**, through dissolution at the air-sea interface. **Marine phytoplankton and other organisms** play a role in consuming dissolved N<sub>2</sub>O.
- **Stratosphere:**
  - In the stratosphere, **N<sub>2</sub>O reacts with ozone (O<sub>3</sub>)**, leading to the formation of **nitrogen oxides (NOx)** and ultimately **nitrogen gas (N<sub>2</sub>)**.

- N<sub>2</sub>O stays in the atmosphere for **longer than the average human lifespan (117 years)**, making it an effective sink for this greenhouse gas, impacting climate and ozone for a longer time.

## What are the Key Findings of the Study?

- **Alarming Rise in Nitrous Oxide (N<sub>2</sub>O) Emission: N<sub>2</sub>O emissions from human activities have increased by 40% (3 million metric tons of N<sub>2</sub>O per year) between 1980 and 2020.**
  - **Top 5 Emitters of N<sub>2</sub>O** were China (16.7%), India (10.9%), US (5.7%), Brazil (5.3%) and Russia (4.6%).
    - Thus, **India is the 2<sup>nd</sup> largest emitter** of N<sub>2</sub>O globally after China.
  - In **Per-Capita terms, India has the lowest per capita emission of 0.8 kg N<sub>2</sub>O/person** lower than China (1.3), US (1.7), Brazil (2.5) and Russia (3.3).
  - The concentration of atmospheric **N<sub>2</sub>O reached 336 parts per billion in 2022**, a 25% rise over pre-industrial levels, more than what was estimated by the [Intergovernmental Panel on Climate Change \(IPCC\)](#).
  - The study points out that currently, **no technologies exist that can remove N<sub>2</sub>O from the atmosphere.**
- **Sources of Nitrous Oxide Emissions:**
  - **Natural Source:**
    - **Natural sources such as oceans, inland water bodies and soil contributed 11.8% of the global emissions of N<sub>2</sub>O between 2010 and 2019.**
  - **Human-Driven Source (Anthropogenic):**
    - **Agricultural activities** were responsible for **74%** of human-driven nitrous oxide emissions.
      - This was mainly due to the application of **chemical fertilisers** and the **use of animal waste on croplands.**
      - The growing use of **nitrogen fertilisers** in the production of food worldwide is increasing concentrations of N<sub>2</sub>O.
    - Other significant sources include **industry, combustion, and waste treatment.**
    - The **growing demand for meat and dairy products** has also contributed to an increase in emissions **through the increase in manure production**, which also causes N<sub>2</sub>O emissions.
- **Rate/Growth of Emissions:**
  - **Emissions from agriculture continue to grow**, while those from other sectors, such as fossil fuels and the chemical industry, are not growing or declining globally.
  - Emissions from **aquaculture are only a tenth of those from the use of chemical fertilisers on land** but are growing rapidly, particularly in China.
- **Emission Pattern in Regions: Among the 18 regions considered in this study, only Europe, Russia, Australasia, Japan and Korea had decreasing nitrous oxide emissions.**
  - Europe had the largest rate of decrease between 1980 and 2020, resulting from reduced fossil fuel and industry emissions.
  - **China and South Asia** had the **largest increases** in N<sub>2</sub>O emissions from 1980 to 2020 at **92%**.

## GLOBAL N<sub>2</sub>O BUDGET

### Key Fact about Nitrous Oxide (N<sub>2</sub>O)

- Nitrous oxide, commonly known as **laughing gas or happy gas**, is a **colourless, odourless, and non-flammable gas**.
- While nitrous oxide is not flammable, it supports combustion to the same extent as oxygen.
- It leads to a **state of euphoria, explaining its nickname, 'laughing gas.'**
- It is **soluble in water**. Its vapours are heavier than air.
- **Applications:**
  - It is commonly used by **dentists and medical professionals** to sedate patients undergoing minor medical procedures.
  - The gas is also used as a **propellant in food aerosols**.
  - It is used in the **automotive industry** to enhance engine performance.

### What are the Implications of Rising Nitrous Oxide Emissions?

- **Intensified Global Warming:** N<sub>2</sub>O is around **300 times more effective than carbon dioxide (CO<sub>2</sub>)** at trapping heat over **100 years**. This magnifies its impact on global warming and its rapid growth adds considerably to atmospheric heat.
- **Threat to Ozone Layer:** N<sub>2</sub>O breaks down in the stratosphere, **releasing nitrogen oxides that damage the ozone layer**, which shields us from harmful **ultraviolet (UV) radiation**.

- This increased UV radiation can lead to a rise in skin cancer, cataracts, and harm to ecosystems reliant on UV protection.
- **Challenge to Food Security: Agricultural sector, particularly the use of nitrogen-based fertilisers, is a major contributor to N<sub>2</sub>O emissions and the growing demand for food will likely lead to a further increase in N<sub>2</sub>O emissions, creating a conflict between food security and climate goals.**
- **Challenge to Paris Climate Agreement:** The increasing level of N<sub>2</sub>O emissions will pose a challenge in achieving the goals of the [Paris Climate Agreement](#) (keeping global warming below 2°C compared to pre-industrial times).

## What are the Proposed Solutions to Mitigate Nitrous Oxide Emissions?

- **Innovative Agricultural Practices:**
  - **Precision Agriculture:** Utilising technologies like **soil sensors** to **optimise fertiliser application** reduces unnecessary nitrogen input, thereby minimising N<sub>2</sub>O formation.
    - A study by Journal Nature found that **precision agriculture techniques can decrease N<sub>2</sub>O emissions by up to 50%.**
  - **Nitrification Inhibitors:** These additives **slow the conversion of ammonium in fertilisers to nitrate**, a readily available form for N<sub>2</sub>O-producing microbes.
  - **Cover Cropping:** Planting cover crops during fallow periods helps retain soil moisture and nitrogen, reducing the risk of N<sub>2</sub>O release.
  - **Using Anti-Methanogenic Feed:** Using Anti-methanogenic feed like '**Harit Dhara**' (**HD**), or developing similar **anti-nitrogen feed** for cattle will help to reduce methane and nitrogen emissions.
    - Additionally, adopting a **cyclic method to generate fuel gas from cattle dung**, instead of allowing nitrogen emissions from anaerobic degradation, can also minimise N<sub>2</sub>O formation.
  - **Using Nano-Fertilisers:**
    - Nano fertilisers can deliver nutrients directly and slowly to plant roots, **minimising excess nitrogen** and **reducing nitrous oxide emissions**. They enhance nutrient absorption, potentially requiring less fertiliser overall. By delivering nutrients slowly and directly to plant roots, they can minimise the surplus nitrogen available for conversion
- **Effective Policy Measures:**
  - **Emission Trading Schemes:** Implementing a **cap-and-trade system for N<sub>2</sub>O emissions** can incentivise industries and farmers to adopt cleaner practices.
    - The successful implementation of such schemes in the **European Union** for other greenhouse gasses offers valuable lessons.
  - **Targeted Subsidies:** Governments can provide financial support for farmers transitioning to sustainable practices that minimize N<sub>2</sub>O emissions.
    - **China's successful reduction in N<sub>2</sub>O emissions** since the mid-2010s has been partly attributed to **targeted subsidies for improved fertiliser management.**
  - **Research and Development:** Increased funding for research on N<sub>2</sub>O mitigation strategies, including **improved fertilisers and waste management techniques**, is crucial for long-term progress.
- **Addressing Emissions from Other Sources:**
  - **Industrial Processes:** Implementing **stricter regulations and promoting cleaner technologies** can minimise N<sub>2</sub>O emissions from industrial sources such as **nylon** production and **nitric acid** manufacturing can curb rising nitrous oxide emissions.
  - **Combustion:** As per the IPCC Climate Change 2021 report, **optimizing combustion processes in vehicles and power plants** can help reduce N<sub>2</sub>O emissions as a by-product.
  - **Waste Management:** As per the [World Bank](#) report, technological advancements in waste-to-energy conversion and the effective **treatment of wastewater and agricultural waste** can significantly decrease N<sub>2</sub>O emissions from these sources.

**Drishti Mains Question:**

What are the reasons for the rise in global nitrous oxide emissions? Discuss the environmental and policy implications of this trend, and suggest measures to mitigate nitrous oxide emissions.

**UPSC Civil Services Examination, Previous Year Question:**

**Q. Which of the following add/adds nitrogen to the soil? (2013)**

1. Excretion of urea by animals
2. Burning of coal by man
3. Death of vegetation

**Select the correct answer using the codes given below:**

- (a) 1 only  
(b) 2 and 3 only  
(c) 1 and 3 only  
(d) 1, 2 and 3

**Ans: (c)**

**Q. Which one of the following sets of elements was primarily responsible for the origin of life on the Earth? (2012)**

- (a) Hydrogen, Oxygen, Sodium  
(b) Carbon, Hydrogen, Nitrogen  
(c) Oxygen, Calcium, Phosphorus  
(d) Carbon, Hydrogen, Potassium

**Ans: (b)**

**Q. Which feature of some species of blue-green algae helps promote them as bio-fertilizers? (2010)**

- (a) They convert atmospheric methane into ammonia which the crop plants can absorb readily
- (b) They induce the crop plants to produce the enzymes which help convert atmospheric nitrogen to nitrates
- (c) They have the mechanism to convert atmospheric nitrogen into a form that the crop plants can absorb readily
- (d) They induce the roots of the crop plants to absorb the soil nitrates in larger quantities

**Ans: (c)**

**Mains:**

**Q. Sikkim is the first 'Organic State' in India. What are the ecological and economical benefits of Organic State? (2018)**
