

## **Decline in Usable Groundwater**

A team from the Indian Institute of Technology (IIT) Kharagpur, West Bengal and Athabasca University, Canada, has compiled the **first estimates of Usable Groundwater Storage (UGWS)** at the state-level across India using both in situ and satellite-based measurements.

- For the compilation, the groundwater-level data was used from 3,907 in situ monitoring wells across the country.
- The compilation includes total UGWS estimation between the years 2005 and 2013.
- Till now, the government agencies have been able to estimate the total groundwater, not the UGWS.
- India is the <u>largest user of groundwater</u> in the world. It uses an estimated 230 km³ of groundwater per year over a quarter of the global total.

## **Key Findings**

- More than 85 % of the groundwater usage in India is linked with irrigation abstraction practices.
- The estimates show rapid depletion of usable groundwater storage during 2005-2013 in most of the northern parts of the country, which lost 8.5 km³ / year of the total groundwater, and the eastern parts which lost 5 km³ /year of the total groundwater.
- Rapid depletion of UGWS in Assam, Punjab, Haryana, Uttar Pradesh, Bihar, and West Bengal.
  - A northeastern state like **Assam** which has always been regarded as a water-affluent; **lost** 2 % of its usable groundwater resource and is at the brink of suffering drought and famine in impending years.
  - Haryana, which gets an annual precipitation of 689 mm, had the highest level of usable groundwater with 3,593 cm while Himachal Pradesh with a precipitation of 1,147 mm per year had the lowest UGWS level of 520 cm.
  - Some pockets in Uttar Pradesh also saw a dip in groundwater table.
  - In these areas, increase in agricultural production has been at the cost of non-renewable loss in the groundwater volume.
- Reasons cited
  - Lack of an organised water supply leads to increased dependence on groundwater.
  - Depletion in groundwater is positively linked with the increased cropping practice of water intensive crops.
  - Overexploitation of the groundwater: About 85 %of rural drinking water needs and 65 %of irrigation needs and 50 %of urban drinking water and industrial needs are fulfilled from the ground water.
- Consequences
  - Rapid depletion in UGWS would accelerate the decline in food production and availability of drinking water, two of the prime goals under UN <u>Sustainable</u> <u>Development Goals 2030</u>. This would affect more than 120 million people in the Gangetic states.
  - Summer groundwater droughts that some states are facing; would intensify in recent future years, will become severe to very severe by 2050, with the possibility of spreading over all the seasons.
  - **Decline in the flow in the adjoining rivers**, including Ganga, thus also impacting riveraquifer interaction.

- Suggestions
  - In order to develop a sustainable groundwater management programme, it is important to **know the exact** <u>water-stress.</u>
  - India needs to develop a much robust quantitative approach, possibly with the help of advanced hydroscience and data science techniques to understand the conjunctive water demands and usages.
- The **southern and western Indian states** like Andhra Pradesh, Maharashtra, Gujarat, Chattisgarh have shown **replenishing usable groundwater storage trends.**
