

Threat to Human Habitation in the Highlands of Kerala

Investigation of **National Centre for Earth Science Studies (NCESS)** scientists in Kerala, in the wake of the **heavy rain and devastating floods in August 2018**, had found that **destabilising geological processes**, coupled with **extreme rainfall events** and **unscientific farming and construction activities**, pose a serious threat to human habitation in the highlands of the state.

- During the investigation in landslide prone areas in Thrissur and Kannur districts of Kerala, the researchers found **huge cracks across farmlands and dwellings**.
 - In the areas surveyed, most of the slopes were used for raising crops and farmers had **blocked the natural drainage systems**.
- **Land subsidence, lateral spread** and **soil piping** were an immediate threat to life and property in the uplands of the state.
 - Heavy intense rainfall triggers slope failure in locations where lateral spread and soil piping have occurred.

//

Destabilising Geological Processes

Soil piping

Refers to the formation of underground tunnels due to subsurface erosion of clay-rich soil by an underground water source, possibly a stream percolating down from the surface through a crack. Soil pipes are known to extend some distance as a continuous channel or as a system of interconnected tunnels that form an extensive, branched network.

Lateral spread

Occurs when the soil on gentle slopes starts moving downhill. It is caused by a process known as liquefaction. When soil loses strength due to saturation, it behaves like fluid, triggering a flow. Lateral spread is progressive and spreads rapidly, often culminating in a complex landslide.

Land subsidence

Is the sinking of the surface soil caused by subsurface erosion, often triggered by unscientific land use and drainage.

- Any developmental activities like construction of roads and buildings in such vulnerable areas require **remedial measures for slope stabilisation**.
- The team apart from outlining the remedial steps also **recommended the formation of a trained task force** for the highlands to monitor ground signatures like hollows, cracks, and water

spouts that often precede land subsidence, lateral spread and landslides.

- Based on the recommendations of the NCESS, the Union Ministry of Earth Sciences (MoES) has initiated steps to establish a **network of landslip monitoring stations** in the highlands.
 - The units based on acoustic emission technology will also have an **early warning mechanism to alert the local community**.

Landslide

- A landslide is defined as the **movement of a mass of rock, debris, or earth down a slope**.
- Landslides are a type of "**mass wasting**", which denotes any down-slope movement of soil and rock under the direct influence of gravity.
- There are 5 main types of landslides:
 - **Falls** are sudden movements of loads of soil, debris, and rock that break away from slopes and cliffs. They occur as a result of mechanical weathering, earthquakes, and force of gravity.
 - **Slides** are a kind of mass movement whereby the sliding material breaks away from underlying stable material.
 - **Topple** encompasses the forward spinning and movement of huge masses of rock, debris, and earth from a slope. It takes place around an axis near or at the bottom of the block of rock.
 - **Spread** takes place on gentle terrains via lateral extension followed by tensile fractures.
 - **Flow** landslide is categorized into earth flows, debris avalanche, debris flow, mudflows, and creep. The most prevalent occurring landslides are rock falls and debris flow.
- While landslides are considered naturally occurring disasters, human-induced changes in the environment have recently caused their upsurge.
- **Natural Causes of Landslides are:**
 - Climatic changes
 - Seismic activities
 - Weathering (natural procedure of rock deterioration that leads to weak, landslide-susceptible materials)
 - Erosion
 - [Volcanic eruptions](#)
 - Steeper slopes
- **Human causes of landslides are:**
 - Mining activities
 - Deforestation

National Centre for Earth Science Studies (NCESS)

- It was established in **1978 by Prof. C. Karunakaran**.
- It operates by the **Earth System Science Organization** under the Ministry of Earth Sciences.
- It **aims to understand the earth in its totality** and gain knowledge on the interactive and competing **processes** that shape the earth, from its evolution to the present status of ever increasing demand for natural resources.
- NCESS **fosters multidisciplinary research in emerging areas of solid earth science** by utilizing the knowledge for earth science applications .
- It is situated at **Thiruvananthapuram in Kerala**.
