

Difficulties in Increasing Life Expectancy

Source: IE

A new study titled "Implausibility of Radical Life Extension in Humans in the Twenty-First Century" reveals that the <u>steady rise in life expectancy</u> driven by medical and technological advancements is now slowing down.

- About the study:
 - Researchers examined life expectancy at birth data from 1990 to 2019, focusing on regions with the highest life expectancy, such as Australia, France, South Korea, Spain, Sweden, and Switzerland.
- Key Findings:
 - The study suggests that the life expectancy in the longest-living regions increased by only 6.5 years between 1990 and 2019.
 - There is a **need for groundbreaking new medicines** that can **slow the ageing process**, rather than simply enhancing treatments for widespread fatal conditions like **heart attacks and cancer**.
 - Current estimates indicate that girls have a 5.3% chance, and boys have a 1.8% chance, of reaching 100 years of age in those regions.
 - However, even if common diseases are eradicated, the decline of organs due to ageing continues to limit significant lifespan extension.
 - Several drugs are being tested to extend lifespan, including metformin, a low-cost <u>diabetes drug</u>, which has been shown to slow ageing in male monkeys.
