

Binary Brown Dwarfs

Source: TH

Recently, researchers discovered that a **brown dwarf** Gliese 229B found in 1995 is actually **two** (binary) brown dwarfs (Gliese 229Ba and 229Bb) orbiting closely around each other while circling a small star.

- This rare <u>binary brown dwarf</u> is located **19 light-years** (1 light year = 9.5 trillion km) away in the **constellation Lepus.**
- It orbits a common red dwarf star with a mass about six-tenths that of our sun.
 - A red dwarf is the smallest, coolest type of star, making up 60-70% of stars in the Milky Way. Its red colour indicates a low temperature.
- About Brown Dwarf: Brown dwarfs are celestial objects between planets and stars, too small for <u>nuclear fusion</u> but larger than the biggest planets like <u>Jupiter</u>.
 - They are capable of burning deuterium (a heavy form of hydrogen) but lack the mass to sustain the fusion of regular hydrogen like stars.
