

Moving Black Hole

Why in News

Scientists have discovered the first moving supermassive black hole whose mass is about three million times that of our Sun.

■ The black hole was travelling within its own galaxy (J0437+2456) which is around 228 million light years away from Earth.

Key Points

- Study Conducted by the Scientists:
 - Scientists studied 10 faraway galaxies with supermassive black holes in the centre, expecting them to have the same velocity as that of the galaxies they reside in.
 - Focus of their study was the water in the accretion disk (the spiralling mass around
 a supermassive black hole made of matter that is eventually ingested by the black hole).
 - As the water circles around the black hole before falling into it like liquid in a sink, it produces a laser-like beam of radio light known as a maser. These masers can tell the velocity of black holes very accurately.
- About the Moving Supermassive Black Hole:
 - Of the 10 black holes they studied, only the one at the center of J0437+2456 was unusual. It was not moving at the same velocity as its home galaxy.
 - Besides the empirical evidence, the **enormous size of these black holes had led people to imagine them to be stationary objects** planted in the middle of galaxies as opposed to objects floating around in space.
 - It is moving with a speed of about 1,10,000 miles per hour inside its galaxy.
 - Possible Causes for the Motion:
 - Two Supermassive Black Holes Merging: Scientists might have spotted the resulting black hole moving in a rearward motion after the merger before settling down in a position.
 - One in a Binary System of Black Holes, where not one but two supermassive black holes might exist within the host galaxy held together by a shared centre of gravity, which they might be orbiting.
 - The twin of the newly-discovered wandering black hole might not be emitting masers, keeping it from being detected by the radio antenna network.

Black Hole

It refers to a point in space where the matter is so compressed as to create a gravity field from which even light cannot escape.

- The concept was theorized by Albert Einstein in 1915 and the term 'black hole' was coined in the mid-1960s by American physicist John Archibald Wheeler.
- Usually, the black holes belong to two categories:
 - One category ranges between a few solar masses and tens of solar masses. These are thought to form when massive stars die.
 - The other category is of supermassive black holes. These range from hundreds of thousands to billions of times that of the sun from the Solar system to which Earth belongs.
- In April 2019, the scientists at the Event Horizon Telescope Project released the <u>first-ever</u> image of a <u>Black Hole</u> (more precisely, of its shadow).
 - The Event Horizon Telescope is a group of 8 radio telescopes (used to detect radio waves from space) located in different parts of the world.
- Gravitational waves are created when two black holes orbit each other and merge.
