

Restraining Mosquito Populations with CRISPR

Why in News

Recently, researchers have created a system that **restrains populations of mosquitoes** by leveraging advancements in [Clustered Regularly Interspaced Short Palindromic Repeats \(CRISPR\)](#)-based [genetic engineering](#).

- Mosquitoes infect millions each year with debilitating diseases such as [dengue](#) and [malaria](#).

Key Points

- **Sterile Insect Technique:**

- SIT is an **environmentally safe and proven technology to suppress wild**

STERILE INSECT TECHNIQUE (SIT)

A method of biological insect control

- To further advance its utility, a novel **CRISPR-based technology, termed precision-guided Sterile Insect Technique (pgSIT)** is described.

- **pgSIT:**

- It is a **new scalable genetic control system that uses a CRISPR-based approach** to engineer deployable mosquitoes that can suppress populations.
 - **Males don't transmit diseases** so the idea is to **release more and more sterile males**.
 - The population of mosquitoes can be suppressed **without relying on harmful chemicals and insecticides**.
- It **alters genes linked to male fertility**—creating sterile offspring—and female flight in *Aedes aegypti*, the mosquito species responsible for spreading diseases including **dengue fever**, [chikungunya](#) and [Zika](#).
- PgSIT mechanically relies on a **dominant genetic technology that enables simultaneous sexing and sterilization**, facilitating the release of eggs into the environment ensuring only sterile adult males emerge.

- The system is **self-limiting and is not predicted to persist** or spread in the environment, two safety features that should enable acceptance for this technology.
- pgSIT **eggs can be shipped to a location threatened by mosquito-borne disease** or developed at an on-site facility that could produce the eggs for nearby deployment.
- Once the pgSIT eggs are released in the wild, sterile **pgSIT males will emerge and eventually mate with females**, driving down the wild population as needed.

▪ **CRISPR:**

- It is a **gene editing technology**, which **replicates natural defence mechanisms in bacteria to fight virus attacks**, using a special protein called Cas9.

- CRISPR-Cas9 technology **behaves like a cut-and-paste mechanism on DNA strands** that contain genetic information. The **specific location** of the genetic codes that need to be changed, or edited, is **identified on the DNA strand**, and then, using the **Cas9 protein, which acts like a pair of scissors**, that location is cut off from the strand.
- A DNA strand, when broken, has a natural tendency to repair itself. Scientists **intervene during this auto-repair process**, supplying the desired sequence of genetic codes that binds itself with the broken DNA strand.
- CRISPR-Cas9 is a simple, effective, and incredibly precise technology with potential to revolutionise human existence in future.
- **Emmanuelle Charpentier of France** and **Jennifer A Doudna of the USA** were awarded the **2020 Nobel Prize in Chemistry** for developing CRISPR/Cas9 genetic scissors.
