

## **Tidal Tail**

## **Source: PIB**

A study led by <u>Indian Institute of Astrophysics (IIA)</u> researchers has revealed the formation of an <u>ultra-diffuse galaxy</u> at the end of the <u>longest tidal tail ever discovered</u>, associated with the <u>galaxy NGC 3785</u>, located 430 million light-years from <u>Earth in the Leo constellation</u>.

- Tidal Tail: A tidal tail is a long, narrow stream of stars and gas created when galaxies interact or merge.
  - Gravitational forces during these interactions pull material from the outer regions of the galaxies, **stretching it into elongated streams** that extend into space.
  - Tidal tails can persist long after the merger, serving as a signature of recent galaxy interactions.
  - These tails provide valuable insights into how galaxies evolve and form stars.
  - Notably, a small portion of a galaxy's stellar formation occurs within tidal tails, highlighting their role in galaxy dynamics and evolution.
- Galaxy NGC 3785: It is a lenticular galaxy located in the Leo constellation, north of
  the celestial equator (imaginary circle that extends from Earth's equator into space), making it
  more visible from the northern hemisphere.
  - A galaxy is a vast collection of gas, dust, stars, and solar systems, held together by gravity. Earth is part of one such galaxy.
